Let's Start!

How can we do a good data validation?

Learning Outcome:

Describe common activities at work to a visitor using short sentences in familiar spoken and written situations.
Understand information about data and its structure in simple spoken and written situations.

Ask your partner:

- How important is setting an appropriate data validation process for an organization?
- How would you avoid issues during the data validation processes?

Can Do Statements:

- I can read and write about smart data validation.
- I can write a short paragraph to describe various forms of smart data validation.
- I can understand information related to smart data validation.

Let's Explore!

Mr. King is explaining to this students what smart data validation is. Can you identify the 3 main elements?

Instructions: Read the text below.

Ok, class. To continue with the class, as you can read in your text about data validation, we can understand that smart data validation comprises the delimitation of the database and the definition of the processing environment; therefore, we can say that validation takes place within them. Now, remember that when we talk about this topic, we not only refer to the storage size or amount of data people store but also to the quality of it. There are several aspects of database design that we don't usually take into account when we define our own database. That's why I'm going to explain the most important aspects you need to consider; but be careful because if you don't understand them well, the rest of the process fails.

As a matter of fact, by the end of this short explanation, I want you to write a short summary about the three main components of the data validation processes. So, as I was saying, we have three basic concepts: definition, ownership, and stewardship. The first one, data definition, determines the description of the data you will validate, its limits, and its relationship to other data. This definition varies depending on each organization and even varies among internal subdivisions of each of these organizations. Take into account that if companies don't define the data properly, it obstructs our work from the beginning.

On the other hand, data ownership concerns the people who make decisions that affect data, such as defining data (data definition) and considering its validity level.

Finally, the third component, data stewardship, concerns all the people who are responsible for data maintenance, from the developers to the users, that is to say, everyone who manipulates the database.

Now that you know what components are there in order to validate data, we move to the requirements of the design section. At this stage, we use data-modeling techniques and set metric-gathering functionality for the different operational processes. Here, you have to evaluate the data model; if you don't do it, your database becomes ineffective, possibly because there can be duplicate information. In such a case, the volume of information in your database increases and affects effectiveness, decreasing the rate at which you can evaluate the required information.

Let's Practice!

It's necessary to understand the concept of data validation

Instructions: Draw a line to match the sentence from Column A to sentence to Column B.

COLUMN A

1. When we talk about smart data validation,
2. If we don't define data,
3. The data ownership is not clear, If you don't
4. If you define the data stewardship in the database,

COLUMN B

- a. it doesn't relate data to those who manipulate and maintain it.
- b. we need to also talk about definition, ownership, and stewardship.
- c. mention the people responsible for the decisions that somehow affect data.
- d. the database doesn't recognize the category or tag each piece of information has.

Let's Practice!

Let's review some concepts

Instructions: Organize the mystery sentences.

1. you / don't / evaluate / data / becomes / ineffective / if / Your / model. / the / database

2. techniques / first. / if / don't / the / modeling / you / Don't / information / data / use / define

3. manipulate / who / stewardship / all / people / and / maintain / the / Data / to / data. / refers

Extension Activity

Is time for you to show how much you remember about data validation processes

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Look for information about the most common forms of data validation.
- Design a poster showing the most relevant ones.
- Explain it to your classmates.

Self-Assessment

- I search for further information about data validation.
- I organize information about data validation.
- I explain the information to my classmates.

Yes No

☐ ☐
☐ ☐
☐ ☐

Target Words

- **duplicate information** (noun): information that appears more than once in a database
e.g. If you don't do it, your database becomes ineffective, possibly because there can be duplicate information.
- **concern** (verb): to relate to or be connected to
e.g. On the other hand, data ownership concerns the people who make decisions that affect data, such as defining data (data definition) and considering its validity level.
- **validity** (noun): the quality of being valid according to specific terms
e.g. On the other hand, data ownership concerns the people who make decisions that affect data, such as defining data (data definition) and considering its validity level.
- **obstruct** (verb): to interrupt the progress of something
e.g. If companies don't define the data properly, it obstructs our work from the beginning.
- **metric-gathering functionality** (noun): function in which metrics for specific data are brought together
e.g. At this stage, we use data-modeling techniques and set metric-gathering functionality for the different operational processes.
- **delimitation** (noun): definition of limits or edges
e.g. We can understand that smart data validation comprises the delimitation of the database.

Learning Points

Zero Conditional in Negative

We use the **zero conditional** to express a result that will always happen.

The **zero conditional** structure consists of two clauses in present simple, one with the conditional particle **if** or **when** and the main clause.

Use the following structure to make a sentence using the first conditional form:

1. **Idea 1 (present simple) + if + idea 2 (present simple)**
2. **If + idea 2 (present simple) + , + idea 1 (present simple)**

Examples:

1. Projects **work** well **if** you **understand** the basic concepts of information.
2. **If** you **understand** the basic concepts of information, projects **work** well.
1. **If** you **compare** the information, it **matches**.
2. Information **matches if** you **compare** it.

In order to make negative sentences using the first conditional form, we add the negative particle "**not**" in the **if clause**. In this case, the existence of such a negative situation propitiates a special fact.

Examples:

1. **If** you **don't organize** the information, the database **becomes** a mess.
2. The database **becomes** a mess **if** you **don't organize** the information.

Examples

- *If companies don't define the data properly, it obstructs our work from the beginning.*
- *If you don't do it, your database becomes ineffective, possibly because there can be duplicate information.*

Learning Points

Countable and Uncountable Nouns to Talk about Data Validation

There are some specific nouns that we use when we talk about smart data validation; some of them are countable and some others are not.
Remember that we divide nouns into countable and uncountable nouns.

Examples:

*I have **two computers** ("Computer" is a countable noun).*

*I have **some information** ("Information" is uncountable; you can't determine it by numbers).*

When we talk about smart data validation, we often use the following countable and uncountable nouns:

Countable Nouns	Uncountable Nouns
Rate	Storage
Amount	Volume
Database	Data
Program	Software
Owner	Ownership

Examples

- *So, as I was saying, we have three basic concepts: definition, ownership, and stewardship.*
- *We can understand that smart data validation comprises the delimitation of the database and the definition of the processing environment.*
- *Data ownership concerns the people who make decisions that affect data.*

Learning Points

Misplaced and Dangling Modifiers

Misplaced and dangling modifiers are words, phrases, or clauses that are in the wrong place modifying the wrong noun.

In English, we have a special way of organizing the words or phrases that we use to determine or describe things and people. If we fail in the correct organization, we could determine or describe the wrong element of the sentence.

Example:

The **wrong** amount of data (The word "wrong" determines the noun "amount")

The amount of **wrong** data (The word "wrong" determines the noun "data")

As you can see in the examples above, there is a difference in meaning between the two sentences. The difference is not so notorious in that case because the sentences are out of a context, but in smart data validation context, the determined data would vary between the two sentences.

Let's use a more basic example:

*Jack drinks a **hot** cup of tea.*

In this sentence, the adjective "hot" is describing the cup and not the beverage, which makes this a weird sentence.

*Jack drinks a cup of **hot** tea.*

In this new sentence, the adjective "hot" is just behind the word "tea" and makes the sentence clear by determining the temperature of the beverage instead of the temperature of the container.
