Let's Start!

How can we avoid issues in data validation?

Learning Outcome:

Describe common activities at work to a visitor using short sentences in familiar spoken and written situations.
Understand information about data and its structure in simple spoken and written situations.

Can Do Statements:

- I can talk about common issues in data validation.
- I can describe how to avoid problems in validation.
- I can identify common problems in validation.

Ask your partner:

- In your opinion, what are the most common problems people find during the data validation processes?
- How do you think we can avoid those problems?

Let's Explore!

Data Validation Issues and How to Avoid Them

Instructions: Read the text below.

Data Validation Issues

When users enter data into any data field of a program or app, the data validation rules try to identify the errors the users are making so that they can reduce their number. The amount of errors the system can identify depends on the validation rules the software developer sets when he develops the app.

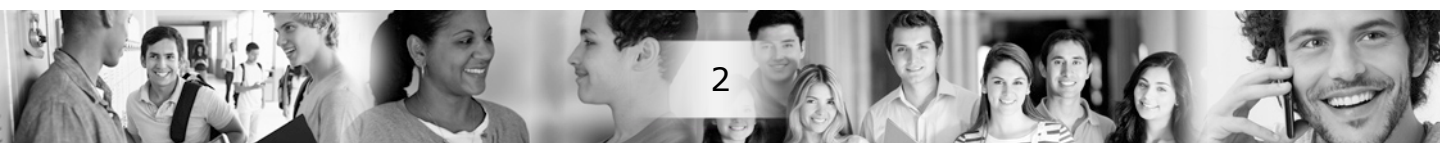

Although it is a highly effective process, any time a user enters data manually, there is a slight chance that he makes an error. If a person misreads what is there on the source document or mishears what other person is telling him, this kind of errors surely occur. These errors also happen when a person rushes and is not careful when typing in the information.

Many transcription errors also happen when people enter data in the form of long codes, like, numbers or letters that does not have any special meaning to the user. An example of this kind of error might be entering "Kile" instead of "Kyle."

There are also transposition errors. These kind of errors occur when the person entering the data changes by accident the order of numbers and letters. For example, typing a 96 instead of a 69.

There are some good methods to avoid this kind of errors. The easiest way to avoid them would be to double-check whatever you enter into a system. You can also enter the data twice, check it on the screen against the original paper document, or you may print out a copy of the data and compare the printout to the original paper document.

Most apps, programs, and systems use data validation tools to guarantee that the data in a database or system contains as few mistakes as possible when the users enter data into the program; avoiding this way any possible validation issues.

Let's Practice!

Can you give me some tips to avoid errors?

Instructions: Underline all the conditional sentences in the paragraph.

There are many methods you can make use of in order to avoid errors. One of those is the double-checking method. **When you double-check your data**, you avoid errors easily. Now, you can also make sure there are not mistakes **if you compare the original document with a printed version of it**. Similarly, Another useful method is the verification one. **If the system allows you to save data in the database**, you make sure it doesn't have any validation issues.

Let's Practice!

Do you recognize these common errors?

Instructions: Organize the mystery sentence.

1. enters / data / can / lead / manually / errors. / a / to / Any / user

2. transposition / order / numbers. / people / the / of / alter / happen / when / errors / Many

3. error / an / to / any / the / don't / meaning / codes / user. / long / when / represent / be / There / also / can

Extension Activity

It's time for you to show how much you know about the topic

Instructions: Complete the following steps. Fill in the Self-Assessment.

- Search for information about data validation methods and processes.
- Identify some common problems people have when they validate data.
- Write down at least 10 ideas of what one should do when facing those problems.
- Share and discuss your ideas with the your classmates and instructor.

Self-Assessment

- I search for information about data validation methods.
- I identify common problems when validating.
- I write down ideas explaining what people should do when facing those problems.
- I share my findings and discuss about the topic.

Target Words

- **printout** (noun): a printed document
e.g. you may print out a copy of the data and compare the printout to the original paper document.
- **source document** (noun): a document to be transcribed to a word processor or to the memory bank of a computer
e.g. If a person misreads what is there on the source document or mishears what other person is telling him, this kind of errors surely occur.
- **transposition** (noun): the act of reversing the order or place of something
e.g. There are also transposition errors.
- **double-check** (verb): to verify; to recheck
e.g. The easiest way to avoid them would be to double-check whatever you enter into a system.
- **misread** (verb): to read inaccurately
e.g. If a person misreads what is there on the source document or mishears what other person is telling him, this kind of errors surely occur.
- **validation rule** (noun): standard used in the process of data validation
e.g. The amount of errors the system can identify depends on the validation rules the software developer sets when he develops the app.

Learning Points

General and Specific Determiners

Determiners are words, such as my, his, the, other, etc., that go at the beginning of a noun phrase. We use them to determine if the noun phrase is specific or general.

When it is clear which thing(s) or person/people you are talking about, you use **specific determiners**.

The most common specific determiners are:
CHART 1

Use **general determiners** to talk about how much stuff or how many things or people you're talking about.

The general determiners are:

Learning Points

Examples

- *When users enter data into any data field of a program or app, the data validation rules try to identify the errors the users are making.*
- *Although it is a highly effective process, any time a user enters data manually, there is a slight chance that he makes an error.*
- *An example of this kind of error might be entering "Kile" instead of "Kyle."*
- *You can also enter the data twice and check it on the screen against the original paper document.*

Zero conditional in affirmative

We use **zero conditional** when we know the result of a condition or action will always be the same.

The structure for the zero conditional is:

If + present simple + present simple

*Example: **If** you **enter** data incorrectly, errors **occur**.*

Notice that after the conditional or if clause (If the data...) you need to place a comma to separate both ideas.

You can also change the order of the two clauses without changing the meaning of the sentence. In this case, there is no need of a comma to separate both ideas.

*Example: Errors **occur if** you enter data incorrectly.*

Examples

- *When users enter data into any data field of a program or app, the data validation rules try to identify the errors the users are making.*
- *If a person misreads what is there on the source document or mishears what other person is telling him, this kind of errors surely occur.*
